Introduction

- ▶ ParSim is a **software tool** developed for:
 - ▶ **Modeling** the traffic of an application
 - ▶ **Reproducing** an arbitrary workload
 - ▶ **Analyzing** its behavior
- ▶ To evaluate performance indices:
 - ▶ **Response time**
 - ▶ **Throughput**
 - ▶ ...
- ▶ Working in **multicore** and **virtualized** environments:
 - ▶ **Parallel** applications
 - ▶ **Pseudo-distributed** services

Motivations

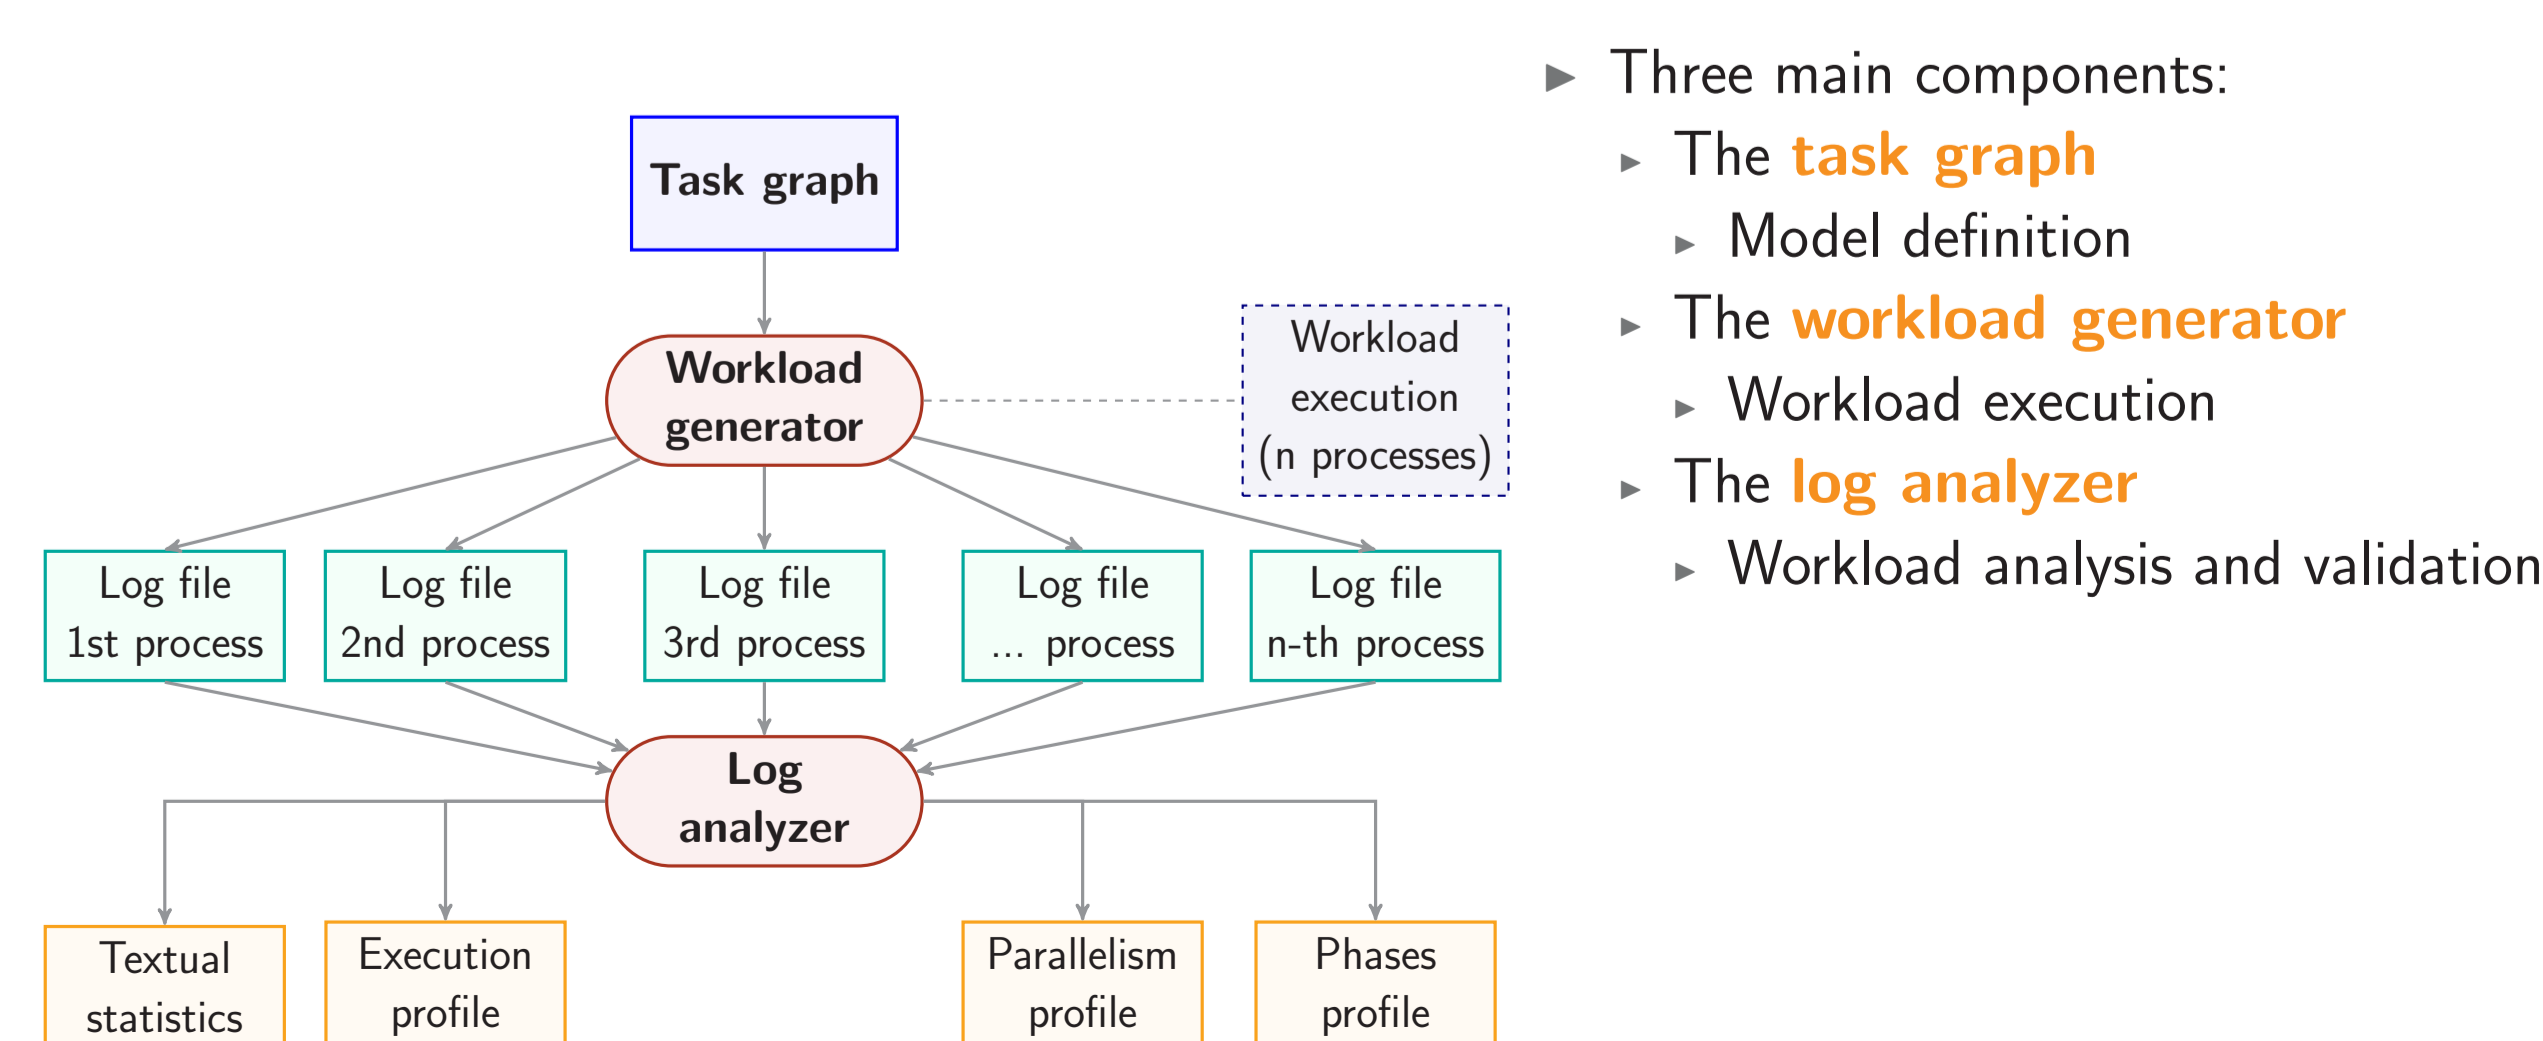

- ▶ Lack of **configurable** benchmarks for parallel environments:
 - ▶ **Specific** workload and **limited configurability**
 - ▶ **Difficult** to customize
- ▶ Need for **specific metrics**
 - ▶ Suitable for parallel environments

Workflow

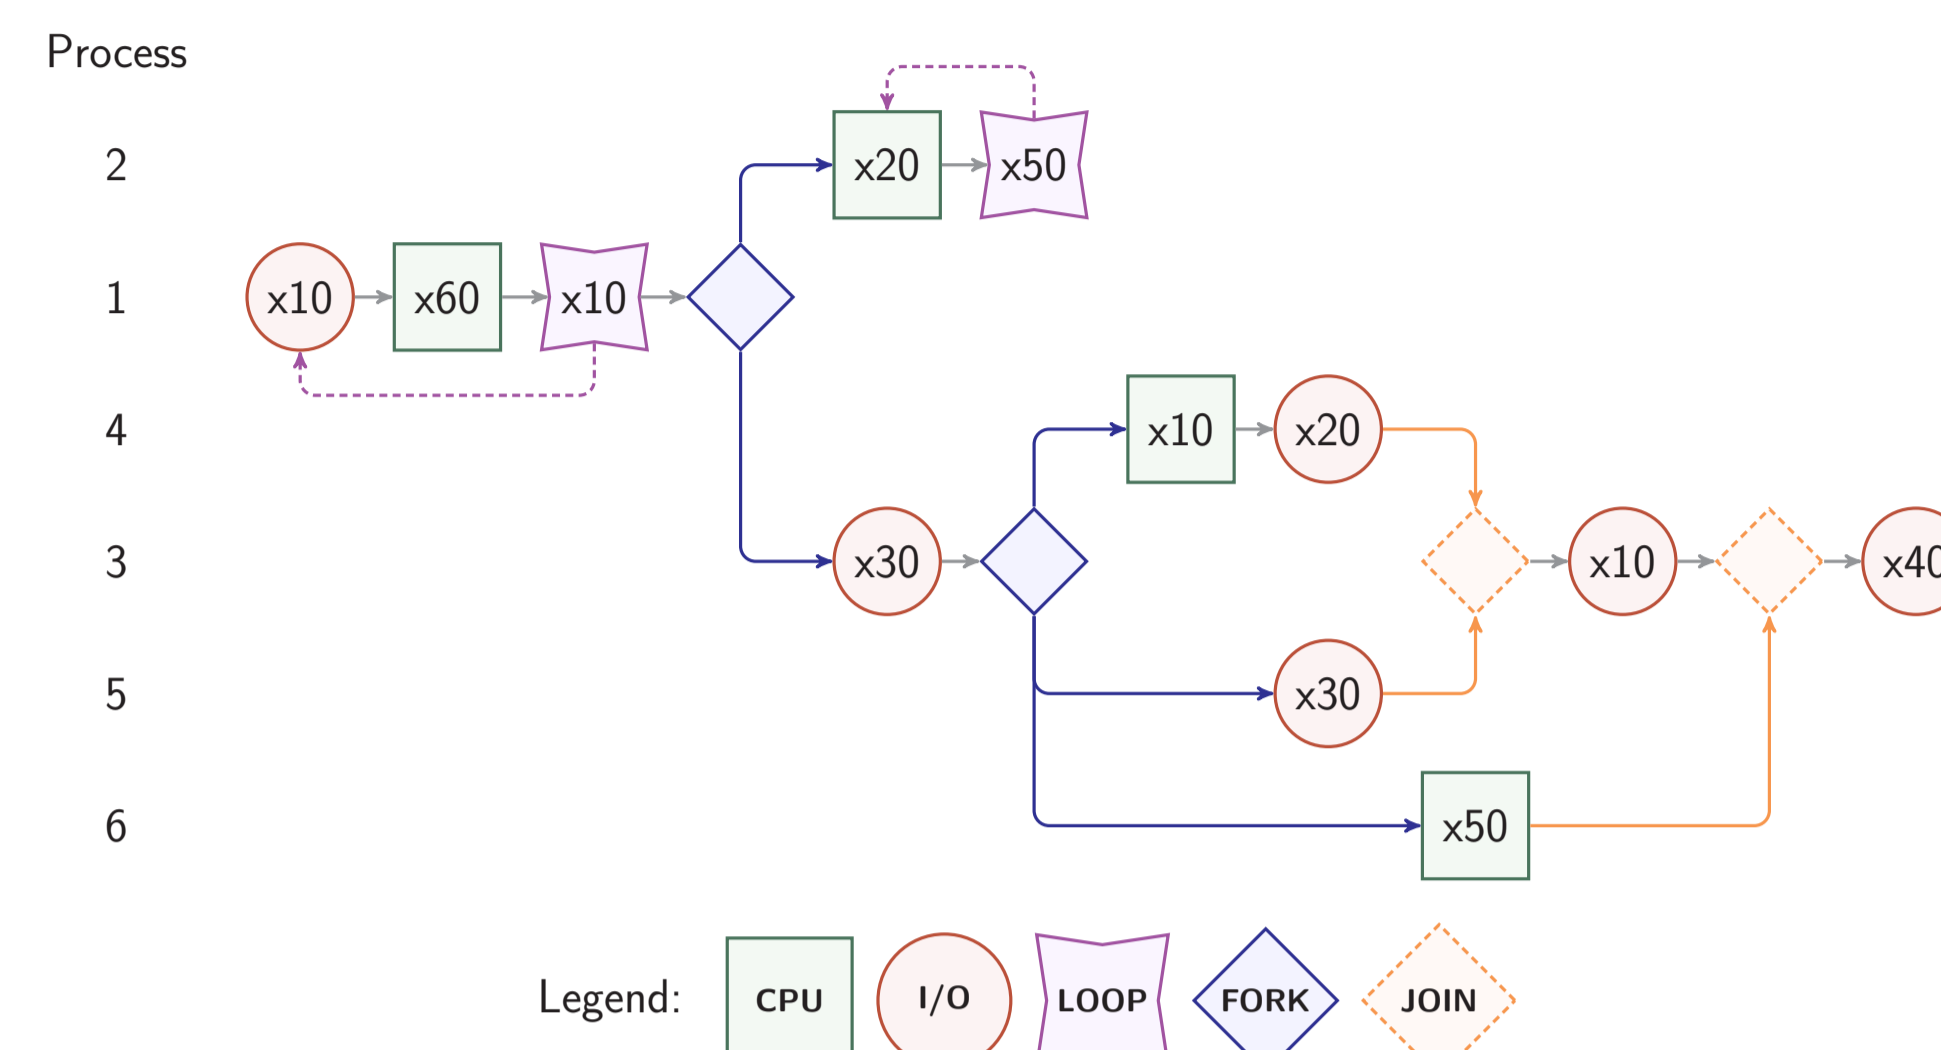

- ▶ **Model definition:**
 - ▶ Derive the original execution model
 - ▶ Task graph **structure**
 - ▶ Iterative fit workload **parameters**
- ▶ **Workload execution:**
 - ▶ Reproduce the **modeled** workload
 - ▶ As specified by the task graph
 - ▶ Profile the workload during the reproduction:
 - ▶ Collect real-time performance and system metrics
 - ▶ Obtain **performance measures** and graphical **temporal profiles** about:
 - ▶ The **execution**
 - ▶ The **processes**
 - ▶ The **phases**
- ▶ **Validation**
 - ▶ Compare original and reproduced workload
 - ▶ Similar behavior

Tool architecture

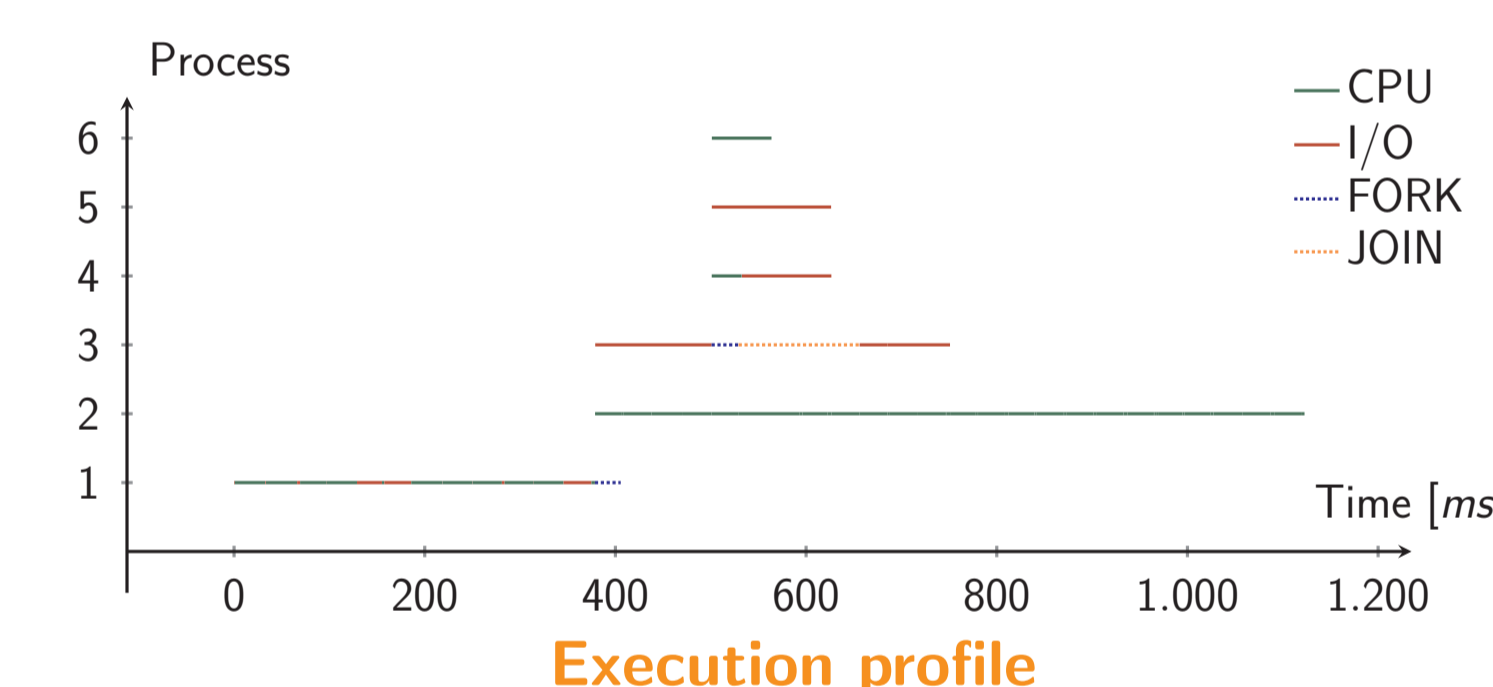

- ▶ Three main components:
 - ▶ The **task graph**
 - ▶ Model definition
 - ▶ The **workload generator**
 - ▶ Workload execution
 - ▶ The **log analyzer**
 - ▶ Workload analysis and validation

Task graph

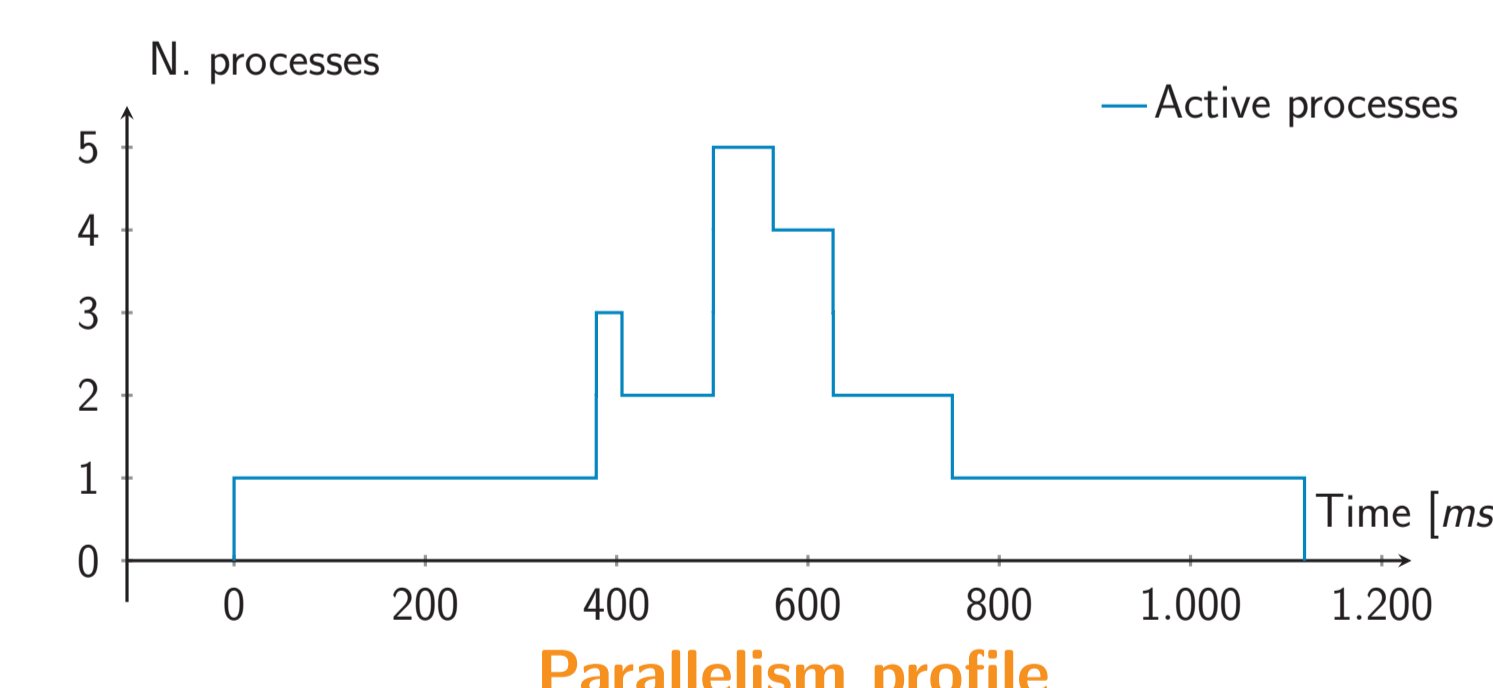

- ▶ Models the **workload** to reproduce
- ▶ Composed by **phases:**
 - ▶ The atomic elements of a task graph
 - ▶ Include the desired **number of operations**
 - ▶ Each phase can be of a single **type:**
 - ▶ CPU-bound; I/O-bound; LOOP; FORK; JOIN
- ▶ ParSim can reproduce complex task graphs:
 - ▶ Alternated CPU-I/O loads
 - ▶ Presence of synchronous and asynchronous processes
 - ▶ Partial synchronizations

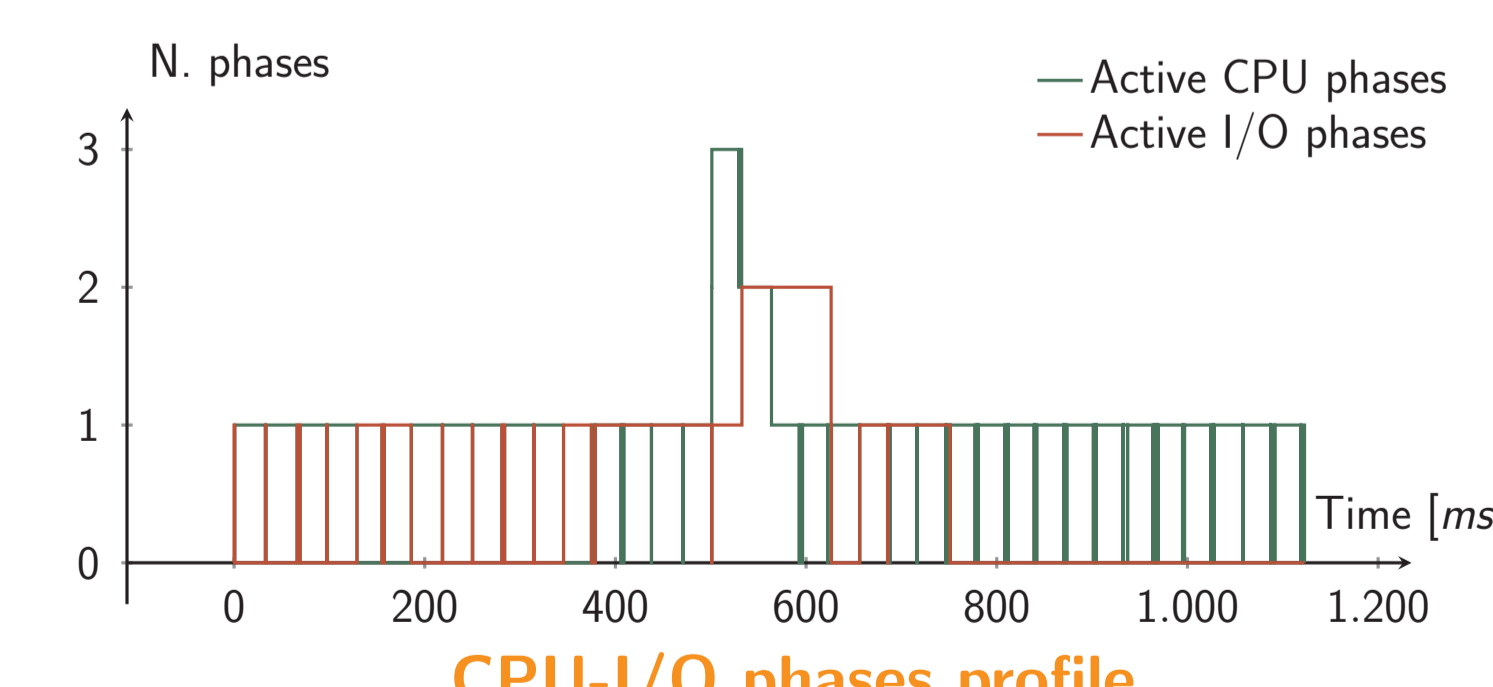

Analysis

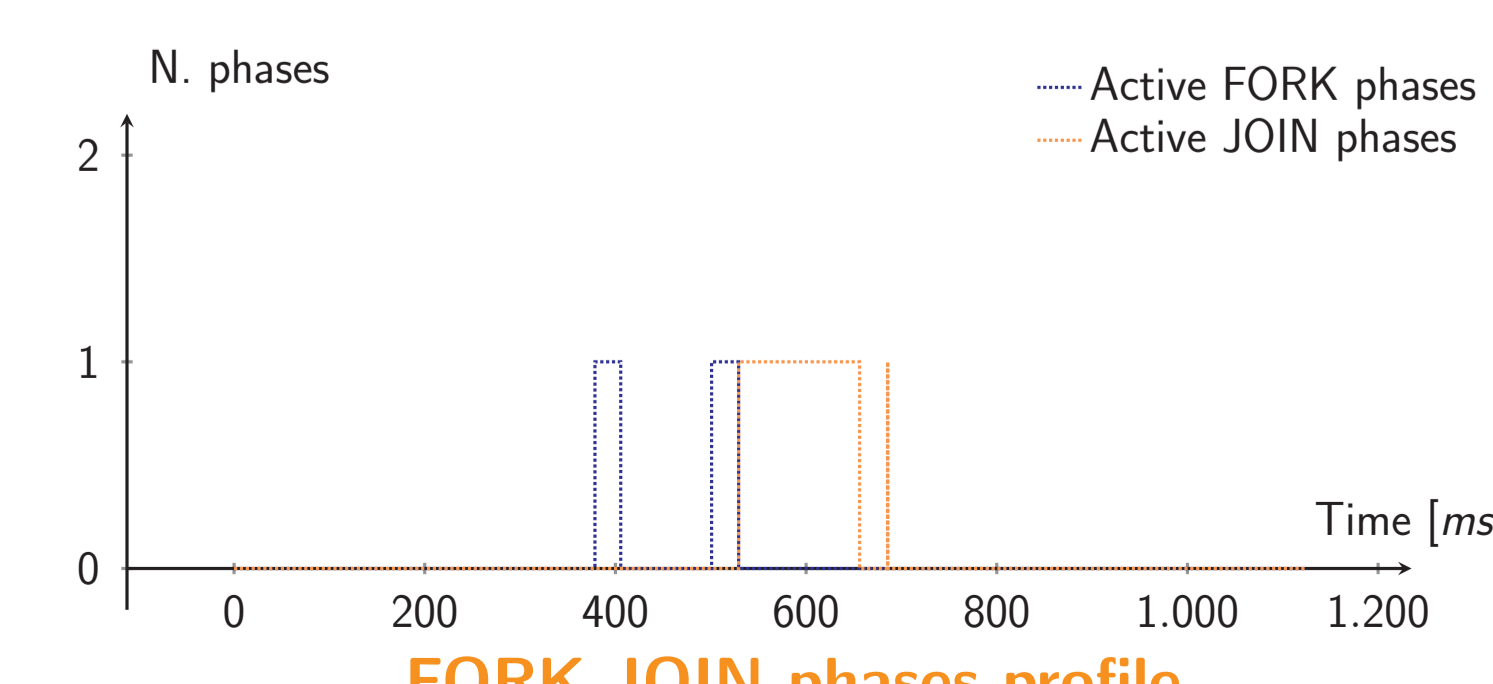

Execution profile

Parallelism profile

CPU-I/O phases profile

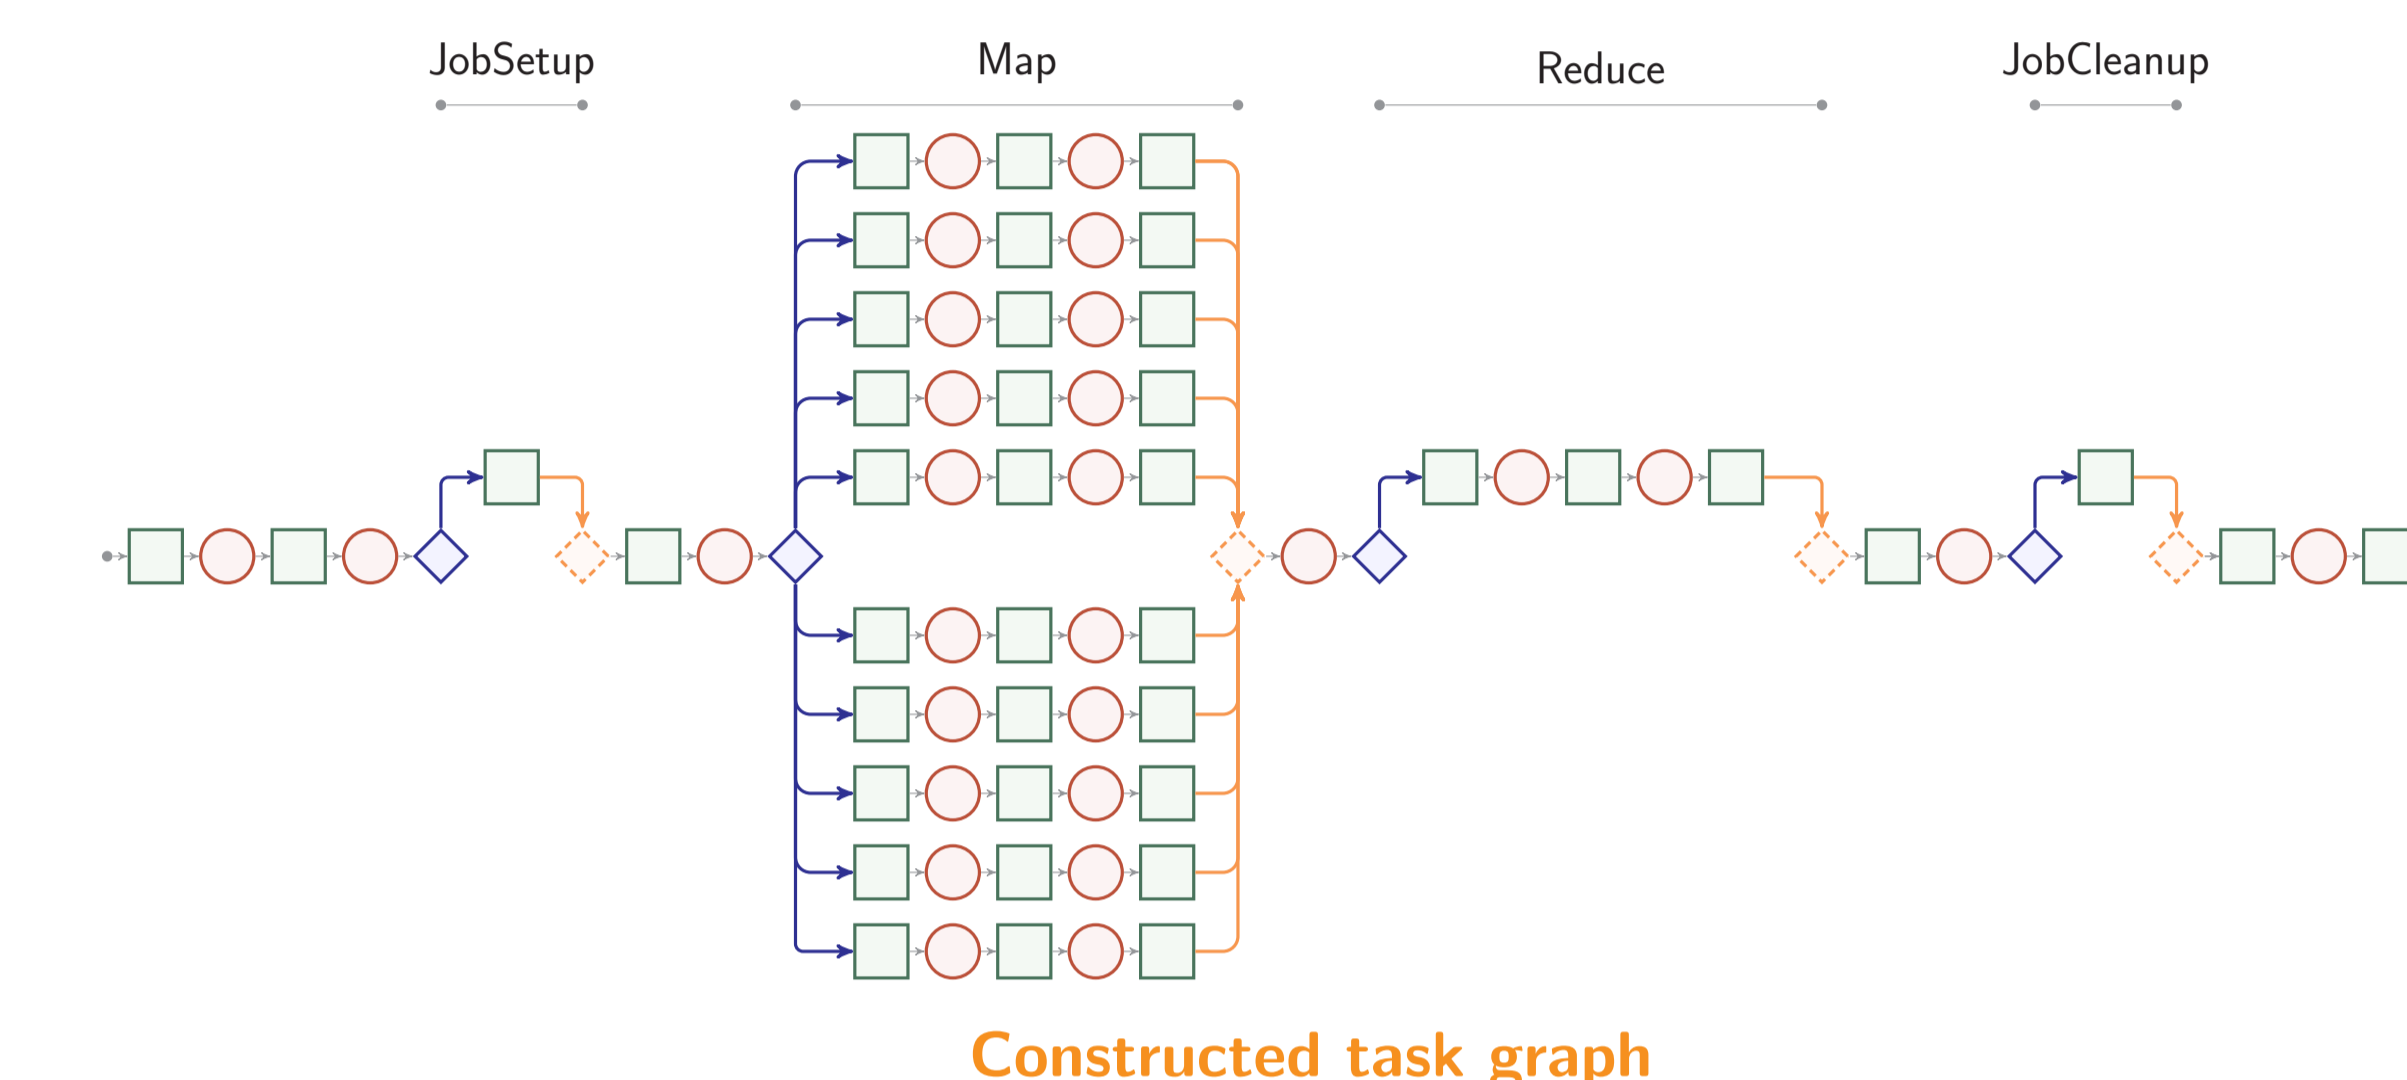

FORK-JOIN phases profile

- ▶ Three graphical **temporal profiles:**
 - ▶ **Execution profile**
 - ▶ Workload evolution over time
 - ▶ State of all processes at each time instant
 - ▶ Impact of concurrent processes on the application behavior
 - ▶ **Parallelism profile**
 - ▶ Number of active processes at each time instant
 - ▶ Real parallelism degree of the application over time
 - ▶ **Phases profile**
 - ▶ Number of active phases at each time instant
 - ▶ Alternation of **CPU-I/O** and **FORK-JOIN** phases
 - ▶ Coexistence of different phases over time
 - ▶ Impact of synchronizations between processes
- ▶ Detailed textual **performance measures**
 - ▶ Several metrics collected for each phase:
 - ▶ **Starting** and **ending** time
 - ▶ Utilized **CPUs**
 - ▶ **Average duration** of each operation
 - ▶ In-depth workload analysis

Case study and validation

1. Model definition
 - ▶ Monitoring the execution through log files
 - ▶ Task graph construction
 - ▶ Parameters fitting
 2. Workload execution and analysis
 3. Validation
 - ▶ Comparison between original and reproduced workload
- ▶ Of a real and publicly available parallel application
 - ▶ Embedded in the **Hadoop MapReduce** framework
 - ▶ Standard *pi* benchmark with 10 mappers and 1 reducer
 - ▶ Set up in a **pseudo-distributed** environment

Constructed task graph

Original workload

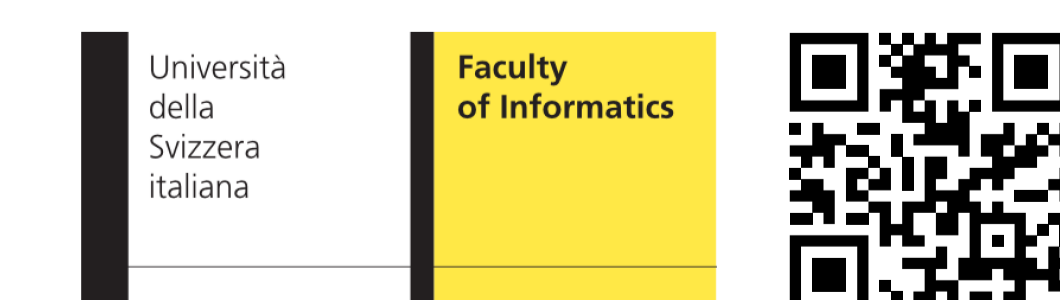

Reproduced workload
